

Heritage Treasures: An In-Depth Analysis of UNESCO World Heritage Sites in Tableau

9.2 – Disadvantages

1. Problems with the quality and consistency of the UNESCO data: The UNESCO datasets have a lot of mistakes like missing information, duplicate entries and wrong details. The names of the sites, countries and coordinates may have spelling mistakes. Are not formatted correctly. The dates are also recorded in ways, which makes it hard to analyze trends. It takes a lot of time and effort to clean and prepare this data before we can even start analyzing it. If we do not handle these problems correctly the final dashboard will have mistaken. Give us wrong information.

2. The risk of making a map that looks nice but does not say much: A common problem with projects that use maps is that they can look really good but not actually say anything useful. The dashboard might just be a map that shows where the sites are. It does not give us any deep insights. People might like how it looks. It will not help us make decisions or find patterns. This means the project is not doing what it promised which is to give us a detailed analysis. We need to put in effort to make sure the dashboard gives us meaningful information that goes beyond just a nice map.

3. The data is not dynamic. Only comes from one source: The list of UNESCO World Heritage Sites does not change very often. New sites are only added once a year. Changes to the list of sites that are in danger do not happen very often. The data does not update automatically which means it will not be relevant for a time. Also, our whole analysis depends on one dataset from UNESCO. If we do not add data from sources our insights will be limited. We will not be able to answer questions about how tourism affects the sites or how climate change or economic factors impact them.

4. Problems with territorial sensitivities: Some of the heritage sites are located in areas that are disputed or contested around the world. If we show these sites on a map, it might look like we are taking a stance even if we do not mean to. People from countries might see the boundaries differently and get offended. This can lead to controversy, negative feedback and damage to our reputation. We need to be careful about how we show the boundaries on the map and add disclaimers to avoid these problems.

5. The project is not very useful for businesses: The project is focused on historical and geographical data, not on business metrics. Companies might not find the dashboard very useful because it does not help them with business problems like optimizing sales, understanding customer behavior or making their operations more efficient. This means the project is not very appealing in a setting where people care about getting a good return on their investment. The project is better suited for educational or non-profit purposes.

6. Challenges with performance and technical issues: The dashboard can be slow because of calculations multiple map layers and interactive filters. A slow dashboard can be frustrating for users. Make them less likely to explore the data. Large datasets can also cause the dashboard to lag or crash in Tableau Public. Additionally, Tableau is not designed to handle amounts of text data like site descriptions, which limits our understanding. Building a high-quality dashboard also requires technical skills, which can be a challenge for people who are just starting out.

7. Data preparation takes a time and can be subjective: The raw UNESCO data needs to be cleaned, restructured and validated which takes a lot of time. Tasks like standardizing country names, correcting coordinates and filling in missing values are time-consuming. Preparing the data often takes effort than actually visualizing it. Furthermore, deciding which sites to highlight and how to categorize the data involves making judgments. Different users might have expectations, which can lead to criticism and make the project seem less objective.
